

AniVault V2

One-page repo-backed app summary

What it is

AniVault V2 is a Qt desktop app for scanning, matching, and organizing an anime library. Repo evidence shows a GUI-only runtime built with PySide6 and launched through **python -m anivault**.

Who it's for

Desktop end users organizing a local anime library. This is an inference from the repo's desktop-app classifier and workflow. Named persona: Not found in repo.

What it does

- Scans local media folders and indexes discovered files.
- Parses anime titles, seasons, episodes, years, and filename-derived resolution.
- Matches parsed title groups against TMDB series data when a TMDB API key is available.
- Supports subtitle-focused organization as a separate GUI mode.
- Builds move plans from matched rows before execution.
- Applies file moves and writes operation logs for executed plans.
- Includes settings and theme controls in the Qt interface.

How it works

- Qt GUI pages and presenters drive the workflow from the main window.
- Bootstrap wiring in **bootstrap/container.py** connects GUI actions to application use cases.
- Use cases cover scan, parse, match, plan, and apply steps.
- Adapters provide filesystem access, TMDB metadata, SQLite-backed repositories, and operation-log storage.
- Data flow is: user selects folders in the GUI -> files are scanned and parsed -> title groups are matched -> a move plan is previewed -> moves are applied and logged.

How to run

- Install: **pip install -e .**
- Optional for TMDB matching: add **TMDB_API_KEY** to a project-root **.env**
- Run: **python -m anivault**

Notes: rollback exists in the repo but is currently a stub. Poppler-based PDF image review was not available in this environment.
